COMP6771 Week 2
STL Containers & Iterators

I/O (Input / Output) in C++

```cpp
#include <iostream>
#include <fstream>

int i;
std::ifstream fin{"data.in"};
while (fin >> i) {
  std::cout << i << "\n";
}
fin.close();
```

```cpp
std::ofstream fout{"data.out"};

fout << i;

fout.close();
```

Better input stream example

```cpp
1  #include <iostream>
2  #include <fstream>
3
4  int main () {
5    // Below line only works C++17
6    if (auto in = std::ifstream{"data.in"}; in) { // attempts to open file, checks it was opened
7      for (auto i = 0; in >> i;) { // reads in
8        std::cout << i << '\n';
9      }
10     if (in.bad()) {
11       std::cerr << "unrecoverable error (e.g. disk disconnected?)\n";
12     } else if (not in.eof()) {
13       std::cerr << "bad input: didn't read an int\n";
14     }
15   } // closes file automatically <-- no need to close manually!
16   else {
17     std::cerr << "unable to read data.in\n";
18   }
19 }
```

I/O (Input / Output) in C++
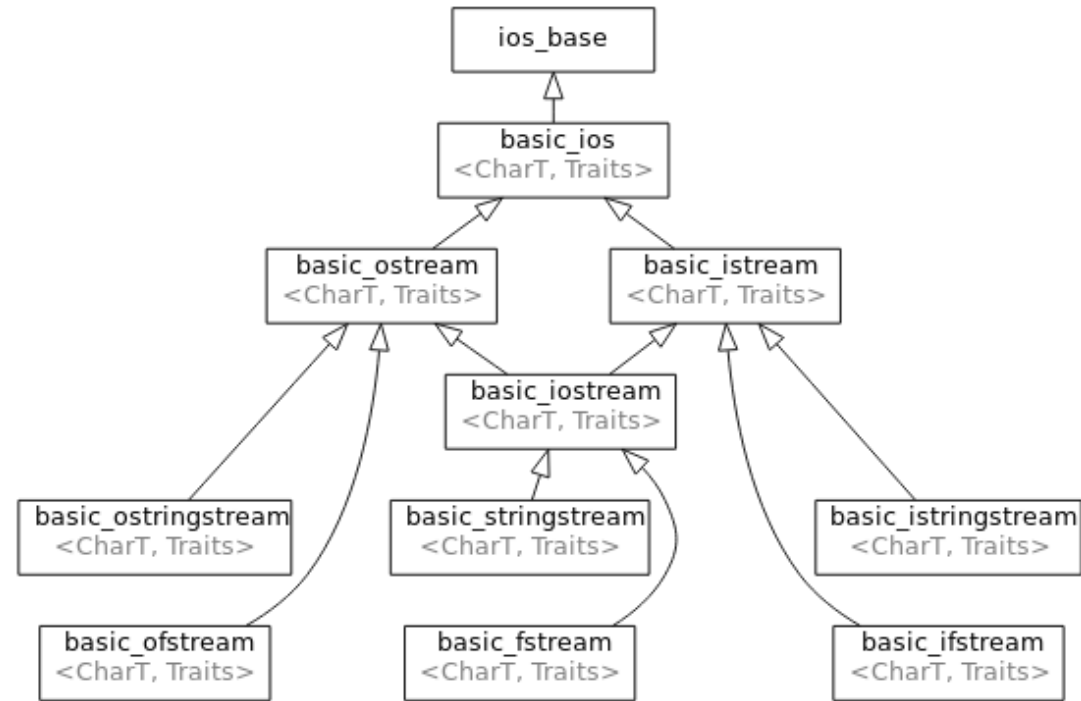

I/O (Input / Output) in C++

Be careful using these, these are not the best style

```cpp
1  #include <iostream>
2  #include <iomanip> // to use the setprecision manipulator
3
4  int main() {
5    std::cout << 1331 << std::endl; // 1331
6    std::cout << "In hex " << std::hex << 1331 << std::endl; // In hex 533
7    std::cout << 1331.123456 << std::endl; // 1331.12
8    std::cout.setf(std::ios::scientific, std::ios::floatfield);
9    std::cout << 1331.123456 << std::endl; // 1.331123e+03
10   std::cout << std::setprecision(3) << 1331.123456 << std::endl; // 1.331e+03
11   std::cout << std::dec << 1331 << std::endl; // 1331
12   std::cout.fill('X');
13   std::cout.width(8);
14   std::cout << 1331 << std::endl; // XXXX1331
15   std::cout.setf(std::ios::left, std::ios::adjustfield);
16   std::cout.width(8);
17   std::cout << 1331 << std::endl; // 1331XXXX
18 }
```

Type Casting

- Types must be known at compile-time
- Type-checking happens at compile-time

```
1 std::string name = "Obama";
2 int age = 17;
3 age = name; // error
```

Type Conversions

- Implicit: Compiler-directed conversions
- Explicit: Programmer-specified conversions

```cpp
1  // Implicit type conversion
2  #include <iostream>
3
4  int main() {
5    int age = 17;
6    double agePrecise = age;
7    std::cout << age;
8  }
```

Type Conversions - Explicit

- This is also known as static casting

```
1  double pi = 3.14;
2  int piInteger1 = pi; // What happens here?
3  int piInteger2 = (int)pi; // C-style
4  int piInteger3 = static_cast<int>(pi); // C++ style
5
6  int x = 5, y = 2;
7  // Note how the order of operations is not immediately obvious with C-style casts
8  double slope = (double)x / y; // C-style
9  double slope = static_cast<double>(x) / y; // C++ style
```

Iterating through arrays in C++

```cpp
1  #include <array>
2  #include <iostream>
3
4  int main() {
5    // C-style. Don't do this
6    // int ages[3] = { 18, 19, 20 };
7    // for (int i = 0; i < 3; ++i) {
8    //   std::cout << ages[i] << "\n";
9    // }
10
11   // C++ style. This can be used like any other C++ container.
12   // It has iterators, safe accesses, and it doesn't act like a pointer.
13   std::array<int, 3> ages{ 18, 19, 20 };
14
15   for (int i = 0; i < ages.size(); ++i) {
16     std::cout << ages[i] << "\n";
17   }
18   for (auto it = ages.begin(); it != ages.end(); ++it) {
19     std::cout << *it << "\n";
20   }
21   for (const auto& age : ages) {
22     std::cout << age << "\n";
23   }
24 }
```

Function Templates

- A **function template** is a **prescription** for the **compiler** to generate particular instances of a function varying by type

  - A function template is **not a function**. It tells the compiler how to generate functions

- We will talk about this in a lot more detail in later weeks

```
1  template <typename T>
2  T Min(T a, T b) {
3    return a < b ? a : b;
4  }
5
6  int main() {
7    Min(1, 2); // uses int min(int, int);
8    Min(1.1, 2.2); // double min(double, double);
9  }
```

STL: Standard Template Library

- STL is an architecture and design philosophy for managing generic and abstract collections of data with algorithms
- All components of the STL are templates
- Containers store data, but don't know about algorithms

- Algorithms manipulate values referenced by iterators, but don't know about containers
STL: Iterators

- Iterator is an abstract notion of a **pointer**
- Iterators are types that abstract container data as a sequence of objects
  - The glue between containers and algorithms

STL: Iterators

- a is a container with all its *n* objects ordered

a.begin() → | 1st | | 2nd | | · · · | | nth | ⌐ ¬ ← a.end()

```cpp
 1 #include <iostream>
 2 #include <vector>
 3 #include <string>
 4
 5 int main() {
 6   std::vector<std::string> names;
 7   for (auto iter = names.begin(); iter != names.end(); ++iter) {
 8     std::cout << *iter << "\n";
 9   }
10   for (std::vector<std::string>::iterator iter = names.begin(); iter != names.end(); ++iter) {
11     std::cout << *iter << "\n";
12   }
13 }
```

- **a.begin()**: abstractly "points" to the first element
- **a.end()**: abstractly "points" to one past the last element
  - a.end() is not an invalid iterator value
- If iter abstractly points to the **k-th** element, then:
  - ***p** is the object it abstractly points to
  - **++p** abstractly points to the (k + 1)-st element

Iterators, Constness, Reverse

```cpp
1  #include <iostream>
2  #include <vector>
3
4  int main() {
5    std::vector<int> ages;
6    ages.push_back(18);
7    ages.push_back(19);
8    ages.push_back(20);
9
10   // type of iter would be std::vector<int>::iterator
11   for (auto iter = ages.begin(); iter != ages.end(); ++iter) {
12     (*iter)++; // OK
13   }
14
15   // type of iter would be std::vector<int>::const_iterator
16   for (auto iter = ages.cbegin(); iter != ages.cend(); ++iter) {
17     //(*iter)++; // NOT OK
18   }
19
20   // type of iter would be std::vector<int>::const_iterator
21   for (auto iter = ages.rbegin(); iter != ages.rend(); ++iter) {
22     std::cout << *iter << "\n"; // prints 20, 19, 18
23   }
24
25   // Can also use crstart and crend
26 }
```

Iterator Categories

Operation	Output	Input	Forward	Bidirectional	Random Access
Read		=*p	=*p	=*p	=*p
Access		->	->	->	-> []
Write	*p=		*p=	*p=	*p=
Iteration	++	++	++	++ --	++ -- + - += -=
Compare		== !=	== !=	== !=	== != < > <= >=

More powerful

Input

Output

Forward

Bidir.

Random

"->" no longer specified as of C++20

Iterator Categories

An **algorithm** requires certain kinds of iterators for their operations

- **input**: find(), equal()
- **output:** copy()
- **forward:** replace(), binary_search()
- **bi-directional**: reverse()
- **random:** sort()

A **container's** iterator falls into a certain category

- **forward:** forward_list
- **bi-directional**: map, list
- **random:** vector, deque

stack, queue are container adapters, and do not have iterators

Other Iterators: Streams

```cpp
1  #include <fstream>
2  #include <iostream>
3  #include <iterator>
4
5  int main() {
6    std::ifstream in("data.in");
7
8    std::istream_iterator<int>begin(in);
9    std::istream_iterator<int> end;
10   std::cout << *begin++ << "\n"; // read the first int
11
12   ++begin; // skip the 2nd int
13   std::cout << *begin++ << "\n"; // read the third int
14   while (begin != end) {
15     std::cout << *begin++ << "\n"; // read and print the rest
16   }
17 }
```

STL: Containers

- STL containers are abstractions of common data structures
- cppreference has a summary of them here.
- Different containers have different time complexity of the same operation (see right)

Operation	vector	list	queue
container()	O(1)	O(1)	O(1)
container(size)	O(1)	O(N)	O(1)
operator[]()	O(1)	-	O(1)
operator=(container)	O(N)	O(N)	O(N)
at(int)	O(1)	-	O(1)
size()	O(1)	O(1)	O(1)
resize()	O(N)	-	O(N)
capacity()	O(1)		
erase(iterator)	O(N)	O(1)	O(N)
front()	O(1)	O(1)	O(1)
insert(iterator, value)	O(N)	O(1)	O(N)
pop_back()	O(1)	O(1)	O(1)
pop_front()		O(1)	O(1)
push_back(value)	O(1)+	O(1)	O(1)+
push_front(value)		O(1)	O(1)+
begin()	O(1)	O(1)	O(1)
end()	O(1)	O(1)	O(1)

O(1)+ means amortised constant time

Sequential Containers

- Elements have specific order controlled by programmer
- These are all templates (but class templates, not function templates)
- Note that vector is still your go-to type for this sort of data. It is typically faster, so don't use another type without a good reason.

Sequential container	Description
std::vector	Dynamically sized array
std::list	Doubly linked list
std::forward_list	Singly linked list
std::deque	<vector> with fast operations for element at beginning
std::array	C-style array wrapper

Vector (Container)

- Array-like container most used is <vector>
  - Abstract, dynamically resizable array
  - In later weeks we will learn about various ways to construct a vector

```cpp
1  #include <iostream>
2  #include <vector>
3
4  // Begin with numbers 1, 2, 3 in the list already
5  int main() {
6    // In C++17 we can omit the int if the compiler can determine the type.
7    std::vector<int> numbers {1, 2, 3};
8    int input;
9    while (std::cin >> input) {
10     numbers.push_back(input);
11   }
12   std::cout << "1st element: " << numbers.at(0) << "\n"; // slower, safer
13   std::cout << "2nd element: " << numbers[1] << "\n"; // faster, less safe
14   std::cout << "Max size before realloc: " << numbers.capacity() << "\n";
15   for (int n : numbers) {
16     std::cout << n << "n"
17   }
18 }
```

Associative Containers

- A **value type** is accessed through a second data type, the **key**.
- Associative containers include:
  - map<T>
    - log(n) for most operations, probably stored as a red-black tree
    - Ordered by key value (requires key to be comparable with <)
    - Iterators will iterate through in order of key, not by insertion time
  - unordered_map<T>
    - O(1) for most operations
    - Stored as a hash table (requires keys to be hashable)
    - Iterators will iterate through in an arbitrary, undefined order
  - set<T>
    - Search, removal, insertion have log(n) complexity
    - Contains sorted set of unique objects of type Key

std::map example

```cpp
1  #include <iostream>
2  #include <map>
3  #include <string>
4
5  int main() {
6    std::map<std::string, double> m;
7    // The insert function takes in a key-value pair.
8    std::pair<std::string, double> p1{"bat", 14.75};
9    m.insert(p1);
10   // The compiler will automatically construct values as
11   // required when it knows the required type.
12   m.insert({"cat", 10.157});
13   // This is the preferred way of using a map
14   m.emplace("cat", 10.157);
15
16   // This is very dangerous, and one of the most common causes of mistakes in C++.
17   std::cout << m["bat"] << '\n';
18
19   auto it = m.find("bat"); // Iterator to bat if present, otherwise m.end()
20
21   // This is a great example of when to use auto, but we want to show you what type it is.
22   for (const std::pair<const std::string, double>& kv : m) {
23     std::cout << kv.first << ' ' << kv.second << '\n';
24   }
25 }
```
